Background and objectives
The American Academy of Pediatrics (AAP) provides recommendations regarding sports in the child with a solitary kidney.¹ They suggest that no restrictions be placed on noncontact sports, and that clinical judgement be used regarding placing any restrictions on contact/collision and limited-contact sports.

A Canadian Urological Association (CUA) guideline on the topic sports and the solitary kidney was initially developed in 2006 in accordance with the 2001 recommendations of the AAP², tailoring them to the young, sports-naïve child. As per the AAP recommendations, a literature search was carried out to determine what evidence is available on the risks of injury to the paediatric kidney through sports and whether these risks might be lowered through sports modification or use of protective gear. A detailed explanation of this literature search and conclusions are available in the Canadian Journal of Urology, June 2006.³ In 2014, the CUA guideline was updated⁴, following a review of updated 2008 AAP recommendations¹, and repeating the methods as described previously.³ The 2014 revision included guidance regarding the operation of all-terrain vehicles. This 2019 revision, produced as a CUA Best Practice Report, was developed following a review of the relevant literature from 2014 to January 2019, and the current position statements of some North American paediatric medical societies. It is noted that there have been no further publications from the AAP on the topic of sports and the solitary kidney since 2012.⁵
Recommendations
In accordance with the AAP recommendations, the following information should be conveyed to
the primary caregiver(s) of a young child with a single kidney. Supporting documentation is
provided following each statement with level of evidence based on the International Consultation
on Urological Diseases (ICUD) system.

Primary caregivers of a young child with a single kidney should be informed of the
following:
1. Their child has only one kidney and loss of that kidney would result in the need for
dialysis or a renal transplant, and lifelong medications
   a. **Evidence:** Indisputable
2. Significant renal injury, of any aetiology, increases the risk/degree of renal insufficiency
   a. **Evidence** – Level 3: High grade renal trauma results in ipsilateral renal scarring
      and volume loss on DMSA renal scan
3. While renal injury can result from contact/collision or limited contact sports, the risks are
   less than the risk of head injury
   a. **Evidence** – Level 3: In American football, which is considered a “collision”
      sport, kidney injuries occur significantly less often than head injuries
   b. **Evidence** – Level 3: Those sporting activities most associated with high-grade
      renal trauma (bicycling, sledding, downhill skiing, snowboarding and equestrian),
      have more than a 5X relative risk of head injury compared to renal injury
4. Primary caregivers should try to keep things in perspective: If they are not going to
   restrict a child from an activity based on the child having only one “head”, then they
   should not restrict the child from that activity based on having only one kidney
   a. **Evidence** – Level 3: Those activities most associated with high-grade renal
      trauma (bicycling, sledding, downhill skiing, snowboarding and equestrian), have
      more than a 5X relative risk of head injury compared to renal injury
5. Wearing protective padding during contact/collision and limited contact sports may
   decrease the risk of renal injury
   a. **Evidence** – Level 4: Although protective padding is available, there is no
      evidence to prove they prevent renal injuries
6. The exact risk of renal injury from each sport is unknown; however, according to
   available studies, bicycling, non-motorized sledding, downhill skiing/snowboarding and
   horse-related activities may carry a higher risk than other activities
      paediatric renal trauma in North America shows that bicycling, sledding, downhill
      skiing, snowboarding and equestrian sports are implicated as the most common
      sports-related causes of high-grade renal trauma
• **Bicycle riding** may be made safer for the child by proper maintenance of the bicycle and handlebars
  1. **Evidence** – Level 3: Minor bicycle crashes can result in serious handle-bar associated injuries.\(^\text{11}\)
  2. **Evidence** – Level 4: As falling onto bicycle handlebars results in renal trauma, it is assumed, but not proven, that proper maintenance of the bicycle and handlebars would help prevent renal injuries.\(^\text{11}\)

• **Sledging** and horse-related activities should be done in a safe manner, ideally with supervision
  1. **Evidence** – Level 4: Most serious sledging injuries occur when sledging is done near or on roadways, when being towed by a motorized vehicle, or when a stationary object is hit. Therefore it is assumed, but not proven, that renal injuries are less likely if sledging is limiting to non-crowded, designated hills, ideally with parental supervision.\(^\text{12,13}\)
  2. **Evidence** – Level 4: It is assumed, but not proven, that horse-related injuries might be prevented if: horses and activities are properly matched to the child’s capabilities; children avoid standing in positions where they might be kicked; and there is parental supervision.\(^\text{14,15}\)

• **Downhill skiing** may be safer than snowboarding. Injuries are more likely to occur in beginners. Formal instruction may be beneficial. Injuries are more likely to occur in inclement weather
  1. **Evidence** – Level 3: When compared, renal injuries were significantly higher in snowboarders than alpine skiers (all ages).\(^\text{16}\) When compared, abdominal injuries were significantly higher in snowboarders than alpine skiers (children).\(^\text{17}\)
  2. **Evidence** – Level 3: Injuries are more likely to occur in beginners (all ages).\(^\text{17}\)
  3. **Evidence** – Level 3: While the overall risk of injury may not be decreased by formal instruction, the risk of potentially severe injuries may be lowered by taking lessons (all ages).\(^\text{18}\)
  4. **Evidence** – Level 3. Overall injury risk is higher when inclement weather affects visibility and snow conditions.\(^\text{19}\)

7. Motor vehicle collisions (MVCs) are a common cause of paediatric renal injury. Therefore, your child should always be in appropriate car restraints and be taught pedestrian and bicycle road safety
a. **Evidence** – Level 3: Review of 7 remote publications (2000–2005), reporting on paediatric renal trauma (all grades) in North America, showed that MVCs (including passenger and pedestrian) resulted in more renal trauma than sporting activities.3

b. **Evidence** – Level 3. Review of 2 recent publications, reporting on paediatric renal trauma (all grades) between the years of 1993-2014, shows that MVCs (including passenger and pedestrian) were responsible for 16'-19% of renal injuries 8.

The use of all-terrain vehicles (ATVs) by children is associated with high grade kidney trauma. However, unlike other recreational activities mentioned in this report, some states in the USA have strict regulations regarding ATV use in children, and a number of paediatric medical societies provide formal recommendations against the operation of all-terrain vehicles by all children less than 16 years of age, regardless of kidney number

a. **Evidence** – Level 3: Renal injuries from 2, 3 and 4 wheeled recreational vehicles are associated with higher grade renal injuries than those caused by bicycle injuries.7

b. **Evidence** – Level 3: Massachusetts has strict state regulations regarding ATV use in children.22 As such, a Boston paediatric trauma center reported no renal injuries secondary to ATV use over a 20 year period (1994-2014).20 This is in comparison to Pennsylvania, where during a similar period (1993-2013), ATV use accounted for 17% of high grade paediatric trauma21

c. Societies recommending against ATV operation in children:
   - American Academy of Pediatrics 201823
   - American Pediatric Surgical Association 201824
   - Canadian Pediatric Society 201225

**Summary**

1. The CUA supports the 2008 recommendations of the AAP that suggest that for children with a solitary kidney, no restrictions be placed on noncontact sports, and that clinical judgement be used regarding placing any restrictions on contact/collision and limited-contact sports

2. Caregivers should be informed about the sports that may carry a higher risk of renal injury and the potential ways to reduce these risks as described in points 5 and 6 above; however, they should also be encouraged to keep things in perspective, as described in point 4 above

3. Children with solitary kidneys should always be placed in appropriate car restraints and be taught pedestrian and bicycle road safety

4. The CUA supports the recommendations of the paediatric societies that recommend against ATV operation in all children as described in point 8 above
