Background and objectives

The American Academy of Pediatrics (AAP) provides recommendations regarding sports in the child with a solitary kidney. They suggest that no restrictions be placed on non-contact sports, and that clinical judgement be used regarding placing any restrictions on contact/collision and limited-contact sports.

This CUA guideline was initially developed in 2006 in accordance with the 2001 recommendations of the AAP, tailoring them to the young, sports-naïve child. As per the AAP recommendations, a literature search was carried out to determine what evidence is available on the risks of injury to the pediatric kidney through sports and whether these risks might be lowered. A detailed explanation of this literature search and conclusions are available. In 2013, this CUA guideline was updated, following a review of the updated 2008 AAP recommendations, and repeating the methods as described previously. New in this revision is guidance regarding the operation of motorized recreational vehicles.

Guidelines

In accordance with the AAP recommendations, the following information should be conveyed to the parent of a young child with a solitary kidney. Supporting documentation is provided following each statement with level of evidence based on the International Consultation on Urological Diseases (ICUD) system.

Parents of a young child with a solitary kidney should be informed of the following:

1. Their child has only one kidney. With current medical advancements, loss of that kidney would result in the need for dialysis or a renal transplant, and lifelong medications.
   a. Evidence: Indisputable.

2. Renal injury, of any etiology, increases the risk/degree of renal insufficiency.
   a. Evidence – Level 3: Children with a normal solitary kidney in childhood have an increased risk of renal insufficiency as an adult.
   a. Evidence – Level 3: Trauma results in a decline of renal function on DMSA renal scan.

3. While renal injury can result from contact/collision or limited contact sports, the risks are less than the risk of head injury.
   a. Evidence – Level 3: In American football, which is considered a “collision” sport, kidney injuries occur significantly less often than head injuries.
   a. Evidence – Level 3: Those sporting activities most associated with high-grade renal trauma (bicycling, sledding, downhill skiing, snowboarding and equestrian), have more than a fivefold relative risk of head injury compared to renal injury.

4. Wearing protective padding during contact/collision and limited contact sports may decrease the risk of renal injury.

Karen Psooy, MD, FRCSC
Division of Pediatric Urology, Winnipeg Children’s Hospital, Winnipeg, MB
6. The exact risk of renal injury from each sport is unknown; however, according to available studies, pedal bicycling, non-motorized sledding, downhill skiing/snowboarding and horse-related activities may carry a higher risk than other activities.3,9,10

a. Evidence – Level 4: Although protective padding is available, there is no evidence to demonstrate that they prevent renal injuries.8

7. Renal injuries from motor vehicle accidents (MVAs) are much more common than injuries from sports activities. Therefore, your child should always be in appropriate car restraints and be taught pedestrian and bicycle road safety.

a. Evidence – Level 3: Review of 7 published articles (2000–2005), reporting all grades of pediatric renal trauma in North America, shows that MVAs (including passenger and pedestrian) result in more renal trauma than sporting activities.3

8. The use of all-terrain vehicles (ATVs) by children is associated with high-grade kidney trauma. However, unlike other recreational activities mentioned in this guideline, there are formal recommendations against the operation of ATVs by all children less than 16 years of age, regardless of kidney number.

a. Evidence – Level 3: Review of 9 published articles (2000–2005) reporting on pediatric renal trauma in North America shows that bicycling, sledding, downhill skiing, snowboarding and equestrian sports are implicated as the most common sport-related causes of high-grade renal trauma.3

• Evidence – Level 3: When compared, renal injuries were significantly higher in snow-boarders than alpine skiers (all ages).16

• Evidence – Level 3: Injuries are more likely to occur in beginners (all ages).17

• Evidence – Level 3: While the overall risk of injury may not be decreased by formal instruction, the risk of potentially severe injuries may be lowered by taking lessons (all ages).17
